Website Structure and Planning

2.3 Sitemap

The sitemap presents the planned navigation structure for the NovaTech Computer Solutions website. The Home page (index.html) acts as the main entry point of the website and provides users with access to the five main content pages: About Us, Products, Services, Enquiry and Contact. Each page has a specific purpose within the website. The About Us page provides information about NovaTech Computer Solutions and its mission, while the Products page presents the computer products and accessories offered by the business. The Services page provides information about the IT support and technical services available to customers. The Enquiry page allows prospective customers to submit requests for product or service information, and the Contact page provides the company's contact details and operating information.

A consistent navigation structure is used so that users can move between the six pages without having to return to the Home page after every visit. This creates a simple and predictable user journey and makes important information easier to locate. The sitemap was also used as a planning guide before the HTML pages were developed, ensuring that the required pages, filenames and navigation relationships were identified before implementation. The filenames shown in the sitemap correspond directly with the HTML files created for the website, which helps maintain consistency between the planning and development stages.

2.4 File and Folder Structure

A clear and organised file and folder structure was planned for the NovaTech Computer Solutions website to ensure that website resources can be located, managed and updated efficiently. The six HTML files are stored in the main website root folder because they represent the primary pages of the website. These files are index.html, about.html, products.html, services.html, enquiry.html and contact.html. Keeping the HTML pages together makes it easier to create and maintain the relative navigation links between the pages.

Separate folders are used for different types of website resources. The images folder stores the visual content used throughout the website, including images for the Home, About Us, Products and Services pages. Keeping images in a dedicated folder prevents the website root from becoming unnecessarily cluttered and allows image paths to follow a consistent format such as images/laptop.jpg. The CSS folder has been created for the Cascading Style Sheets that will be introduced during the styling stage of the project, while the js folder has been prepared for JavaScript files that may be introduced during later development.

Consistent lowercase filenames are used throughout the project to reduce errors when creating hyperlinks and referencing resources. This is particularly important because incorrect filenames or file paths can result in broken navigation links or images that fail to display. The organised structure also separates website content, presentation resources and scripting resources, making the project easier to maintain as the website develops through later stages.

The implemented file and folder structure shown below provides evidence that the planned structure was created in the project directory. It contains the six required HTML pages together with the images, CSS and js folders. This structure provides an organised foundation for the continued development, styling and testing of the NovaTech Computer Solutions website.

Implemented Website File and Folder Structure

2.5 HTML Development

The NovaTech Computer Solutions website was developed using HTML5 based on the sitemap and file structure established during the planning stage. The website consists of six interconnected pages: Home, About Us, Products, Services, Enquiry and Contact. Each page was created for a specific purpose while maintaining a consistent structure and navigation system across the website.

HTML5 was used to structure and present the website content, including headings, paragraphs, lists, hyperlinks, images and form controls. Semantic HTML elements were incorporated to divide each page into meaningful sections and make the source code easier to understand and maintain. Relative hyperlinks connect the six HTML pages, allowing users to navigate throughout the website without relying on external or absolute file paths. Images stored in the dedicated images folder are referenced using relative paths so that the website remains portable when the complete project folder is moved to another computer or submitted for assessment.

At this stage of development, the focus is on establishing the website structure, basic content, navigation and functionality using HTML5. The separate css and js folders have been prepared for later stages of development, allowing presentation and scripting resources to be introduced without changing the organised structure of the project.

2.5.1 HTML5 Website Structure

The NovaTech Computer Solutions website was developed as six interconnected HTML5 pages consisting of Home (index.html), About Us (about.html), Products (products.html), Services (services.html), Enquiry (enquiry.html) and Contact (contact.html). Each page follows a consistent structural approach so that users experience similar navigation and page organisation throughout the website.

Semantic HTML5 elements were used to give meaning and structure to the content. The <header> element identifies the introductory area of the pages and contains the NovaTech Computer Solutions identity and tagline. The <nav> element contains navigation links to the six pages, allowing users to move between different areas of the website. The <main> element contains the primary content of

each page, while <section> elements divide related information into logical content areas. The <footer> element is used at the bottom of the pages for the website's closing information.

Different HTML elements were selected according to the type of information being presented. Headings establish a clear content hierarchy, paragraphs provide descriptions and supporting information, and unordered lists organise related products, services and other information. Hyperlinks connect the website pages, while elements display the visual content stored in the images folder. Descriptive alt text is included with images to provide a textual description of their content.

The Enquiry page also makes use of HTML form elements to collect information from users. Form controls allow users to enter their details and enquiry information, while required-field validation helps prevent the form from being submitted when compulsory information has not been provided. This provides basic form functionality using HTML before more advanced styling or scripting is introduced in later development stages.

Descriptive HTML comments were also included within the source code to identify important sections and make the code easier to read and maintain. Together, these elements provide a structured foundation for the NovaTech website while keeping the HTML organised for later development.

2.5.2 Website Pages and Browser Testing

After the HTML5 structure and content were completed, the NovaTech Computer Solutions website was tested in a web browser to verify that the six pages displayed correctly and that users could navigate successfully throughout the website. Testing was important because errors in filenames, hyperlinks or relative file paths could prevent pages or images from loading correctly.

Each navigation link was tested by moving between the Home, About Us, Products, Services, Enquiry and Contact pages. The links were checked to confirm that they directed users to the correct HTML files and that there were no broken navigation paths. The consistency of the navigation menu across the different pages was also checked to ensure that users could access the main sections of the website from each page.

The website images were tested to confirm that they loaded from the images folder using the correct relative file paths. The displayed images were also checked against their respective page content to ensure that they were relevant to the information being presented.

The Enquiry page received additional functional testing because it contains an HTML form. The form fields were checked to confirm that users could enter the required information. Required-field validation was tested by attempting to submit the form without completing compulsory fields. The browser correctly prevented incomplete submission, confirming that the HTML validation was functioning as intended.

Screenshots of the completed pages were captured as evidence of browser testing. Figures 3 to 8 below demonstrate the appearance of the Home, About Us, Products, Services, Enquiry and Contact pages during testing. These screenshots provide visual evidence that the planned six-page website structure was successfully implemented in HTML5.
